

# Machine Learning Development Life Cycle (MLDLC)

The video introduces the **Machine Learning Development Life Cycle (MLDLC)**, a structured set of guidelines for building machine learning-based software products. The MLDLC is a **cyclic process** designed to systematically identify problems, develop solutions, and continuously improve machine learning systems.

## Major Steps in the MLDLC

### 1. Framing the Problem

This initial step focuses on clearly defining the problem to be solved. It includes:

- Identifying the target customers
- Estimating costs and required team size
- Visualizing the final product
- Deciding whether the problem requires supervised or unsupervised learning
- Selecting suitable algorithms
- Identifying potential data sources

### 2. Gathering Data

Data is the foundation of any machine learning system. This step involves collecting data from various sources such as:

- CSV or Excel files
- APIs
- Web scraping
- Databases
- Big data tools like Hadoop

The collected data must be stored in a format suitable for further processing.

### 3. Data Pre-Processing

Raw data is often incomplete, inconsistent, or noisy. Data pre-processing ensures the data is ready for model training by:

- Removing duplicate records

- Handling missing values
- Correcting errors or inconsistencies
- Scaling and normalizing values

This step ensures the data can be effectively consumed by machine learning algorithms.

## **4. Exploratory Data Analysis (EDA)**

EDA helps in understanding the structure and characteristics of the data. It involves:

- Visualizing data using graphs and charts
- Performing univariate, bivariate, and multivariate analysis
- Detecting outliers
- Handling class imbalance

The goal is to gain meaningful insights and build a solid understanding of the relationship between inputs and outputs.

## **5. Feature Engineering and Feature Selection**

### **Feature Engineering**

This involves creating new and more informative features from existing data to:

- Simplify analysis
- Improve model accuracy and performance

### **Feature Selection**

This step reduces the number of features by removing irrelevant or redundant ones, which:

- Improves model efficiency
- Reduces training time

## **6. Model Training, Evaluation, and Selection**

### **Model Training**

Multiple machine learning algorithms are trained using the prepared dataset to identify the best-performing model.

### **Model Evaluation**

Models are evaluated using appropriate metrics such as:

- Classification accuracy
- Mean Squared Error (MSE)
- Silhouette index

## **Model Selection**

The best-performing model is selected and further improved through:

- Hyperparameter tuning
- Ensemble learning techniques such as bagging, boosting, and stacking

## **7. Model Deployment**

The trained model is converted into a usable software product that users can interact with. This may involve:

- Creating a binary model file
- Deploying the model as an API
- Hosting it on cloud platforms such as AWS, GCP, or Heroku

Deployment allows the model to be integrated into web, mobile, or desktop applications.

## **8. Beta Testing**

The model is released to a limited group of users to collect feedback. This phase:

- Uses A/B testing to compare performance
- Identifies issues or improvement areas
- May require revisiting earlier stages of the lifecycle

## **9. Optimizing the Model**

After successful testing, the model is launched to all users. Continuous optimization includes:

- Backing up the model and data
- Automating model re-deployment
- Managing load balancing
- Deciding on re-training frequency
